Use of Statins after ICH

Ashkan Shoamanesh, MD, FRCPC

Associate Professor of Medicine (Neurology)

Marta and Owen Boris Chair in Stroke Research and Care

Director, Hemorrhagic Stroke Research Program

McMaster University / Population Health Research Institute

ı, Canada

Disclosures

- Co-Chair and Canadian National PI of SATURN trial (NIH-StrokeNet) and Co-PI of SATURN MRI substudy (NIA)

Objectives

- Discuss the clinical dilemma surrounding the use of statins in patients with ICH
  - Epidemiologic data correlating cholesterol levels and ICH
  - Mendelian randomization analyses
  - RCTs
- Review alternative lipid lowering therapies in this population
- Highlight the ongoing SATURN RCT

Statins in Vascular Prevention

	ACEI (HOPE)	Lipid lowering (1 mmol/L)	DAPT (PEGASUS; ticagrelor 60 mg BID)	BP lowering (10 mmHg)	COMPASS Rivaroxaban 2.5 mg BID + ASA
Composite of efficacy outcomes	–18%	–21%	–16%	–20%	–24%
Death	–14%	–9%	–17%*	–13%	–18%
Stroke	–23%	–15%	–25%	–27%	–42%
MI	–18%	–24%	–16%	–17%	–14%*
MALE	–11%*	–	–35%	–	–46%

*Not significant

ACEI, angiotensin-converting-enzyme inhibitor; ASA, acetylsalicylic acid; BID, twice daily; BP, blood pressure; DAPT, dual antiplatelet therapy; MALE, major adverse limb event; MI, myocardial infarction

Statin use in Canada

- 10% of Canadians are taking statins
  - 1 in 4 should be as per CCS guidelines

phy (CAT), etc. Moreover, in fatal cases,
autopsy it may be difficult to distinguish ac-
between subarachnoid hemorrhage, due to
aneurysm, primary hypertensive in-
al hemorrhage and secondary hemorrhage
omboembolic cerebral infarction especially if
s been extensive destruction of brain and
structures. With ischemic cerebral infarction,
hard to be sure whether infarction is due to
sis or embolism.
e these difficulties, studies have been carried
under way often in conjunction with studies

that of Whites in the United States. In fig
tality data for the year 1970 are show
several populations with rates age-adjuste
the age of the Hawaiian population in 19

When the ABCC mortality data were
with those for the Hawaii and California
the same age groups, it was found that s
tality in Japan was 3 times that of the
American cohorts.[10] Stroke prevalence als
pared in the 3 study sites and the
remarkably similar to the mortality ratio

A comparison of strokes found at first ex
subdivided into those due to infarction an

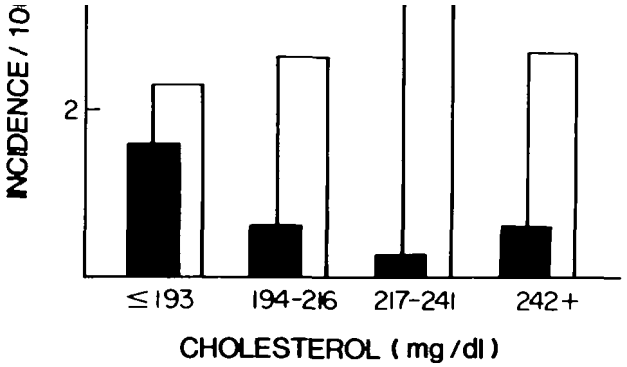

FIGURE 7. *Incidence of stroke by quartile of serum cholesterol.*

193 mg/dl = 5 mmol/L

It appears to be a universal finding among all stroke epidemiology studies that the single most important risk factor for stroke, whether of cerebral infarction or of intracranial hemorrhage, is hypertension. In addition, Paffenbarger, et al.,[37] in a study of California longshoremen, found heart disease and abnormal glucose metabolism as factors increasing stroke mor-

e United States. In figure

Fatal myocardial infarction	1 (0.1)	1 (0.1)	—	
Other cardiovascular death	7 (0.5)	6 (0.4)	—	
Sudden death of undetermined origin	6 (0.4)	11 (0.8)	—	
Nonfatal cerebral infarction or stroke of undetermined origin	81 (5.7)	100 (7.0)	—	
Nonfatal acute coronary syndrome	15 (1.0)	23 (1.6)	—	
Urgent coronary revascularization	5 (0.3)	6 (0.4)	—	
Urgent carotid revascularization	3 (0.2)	3 (0.2)	—	
Secondary end points				
Myocardial infarction or urgent coronary revascularization — no. (%)	20 (1.4)	31 (2.2)	0.64 (0.37–1.13)	0.12†
Cerebral infarction or urgent revascularization of carotid or cerebral artery — no. (%)	88 (6.2)	109 (7.6)	0.81 (0.61–1.07)	
Cerebral infarction or TIA — no. (%)	120 (8.4)	139 (9.7)	0.87 (0.68–1.11)	
Any revascularization procedure — no./total no. (%)‡	94/1430 (6.6)	99/1430 (6.9)	0.93 (0.70–1.24)	
Carotid artery	17/94 (18)	23/99 (23)	—	
Coronary artery	44/94 (47)	51/99 (52)	—	
Peripheral artery	33/94 (35)	25/99 (25)	—	
Death — no. (%)				
Cardiovascular cause	22 (1.5)	32 (2.2)	0.69 (0.40–1.18)	
Any cause	88 (6.2)	93 (6.5)	0.97 (0.73–1.30)	
Cerebral infarction or intracranial hemorrhage — no. (%)	103 (7.2)	126 (8.8)	0.82 (0.63–1.07)	
Intracranial hemorrhage — no. (%)	18 (1.3)	13 (0.9)	1.38 (0.68–2.82)	
Newly diagnosed diabetes — no. (%)§	103 (7.2)	82 (5.7)	1.27 (0.95–1.70)	

* The hazard ratio for the primary end point was adjusted for the index event (stroke or transient ischemic attack [TIA]), the time since the index event, sex, and age. Missing values for covariates were handled with the use of a multiple-imputation technique in 37 patients (1.3%). The unadjusted hazard ratio was 0.77 (95% confidence interval [CI], 0.61 to 0.97; P=0.03). Confidence intervals have not been adjusted for multiple comparisons and cannot be used to infer treatment effects.

† P values for additional secondary end points were not calculated after there was no significant between-group difference for the first end point on hierarchical testing.

‡ The percentage of patients who underwent each revascularization procedure has been rounded because the overall denominator of patients in each category is less than 100.

§ Patients in whom diabetes had not been diagnosed at baseline were categorized by investigators as having newly diagnosed diabetes if they had at least two measures of fasting glucose of 126 mg per deciliter (7.0 mmol per liter) or more or a glycated hemoglobin value of 6.5% or more at a follow-up visit. This classification was not adjudicated.

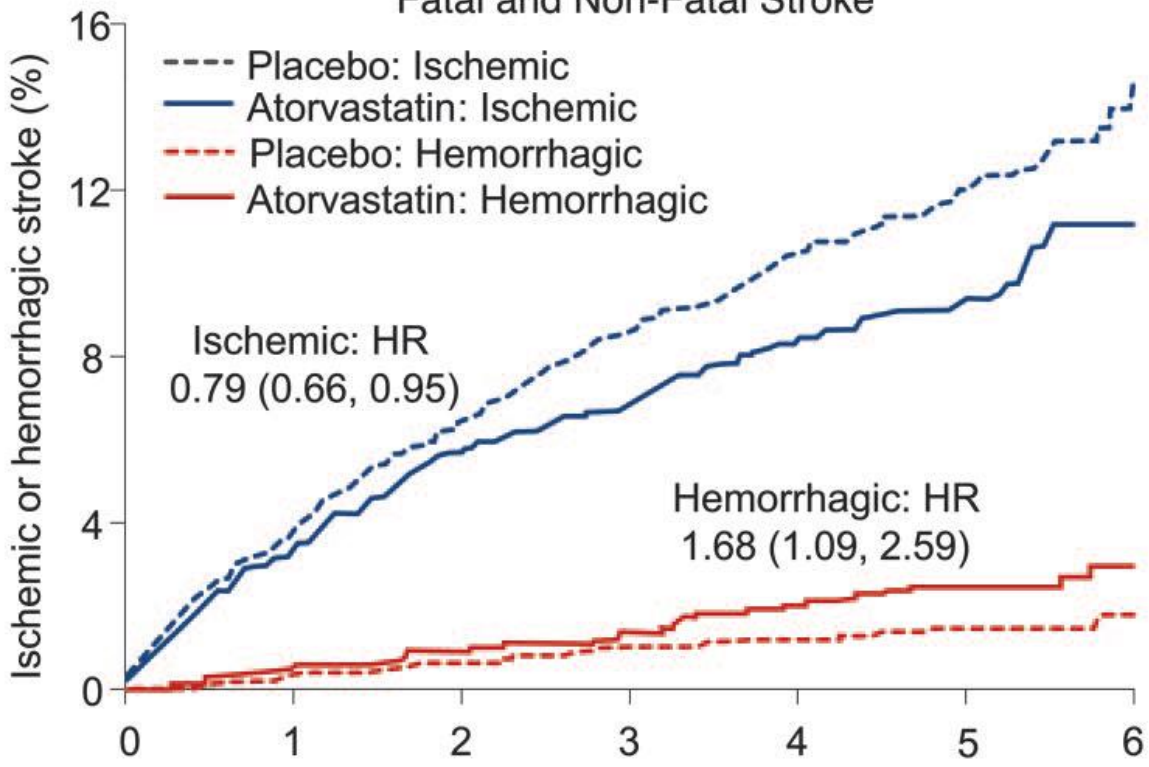

Figure 1. Low-Density Lipoprotein (LDL) Cholesterol Levels over Time.
Shown are median values in the two study groups; I bars indicate 95% confidence intervals. Below the graph, the absolute and percentage reductions in LDL cholesterol level in the evolocumab group are compared with those in the placebo group and are presented as least-squares means or means (details are provided in the Methods section in the Supplementary Appendix). To convert the values for cholesterol to millimoles per liter, multiply by 0.02586.

locumab =13,784)	Placebo (N=13,780)	Hazard Ratio (95% CI)	P Value*

[a]Inverse variance fixed effects meta-analysis of logistic regression results for intracerebral hemorrhage (ICH) across Genetics of Cerebral Hemorrhage with Anticoagulation (GOCHA), International Stroke Genetics Consortium ICH (ISGC-ICH) genomewide association study (GWAS), and Genetic and Environmental Risk Factors for Hemorrhagic Stroke (GERFHS). For each study, the logistic regression model used ICH risk as the dependent variable and a polygenic risk score as the independent variable, adjusting for age, sex, and 4 principal components. The PRS were normalized and entered to the model as a continuous predictor. The OR represents the change in the odds of ICH per each additional SD of the PRS.

[b]Mendelian randomization results of genetically instrumented cholesterol levels using a polygenic risk score as the instrument. Each lipid fraction-specific analysis utilized the ratio method, taking the effect estimates for ICH ~ PRS (numerator) and lipid level ~ PRS (denominator).

CI = confidence intervals; ICH = intracerebral hemorrhage; LDL = low-density lipoprotein.; OR = odds ratio; PRS = polygenic risk score.

[2]Division of General Internal Medicine and Center for Clinical Effectiveness, University of Cincinnati, PO Box 670535, Cincinnati, OH 45267-0535

Results of Base Case Decision Analysis

Prior ICH Location	Setting Effectiveness (QALYs)	No Statin	Statin RR 1.68
Lobar ICH	Primary prevention	6.8	4.6
	Prior MI	6.2	4.4
	Prior ischemic stroke	6.0	4.2
Deep ICH	Primary prevention	13.0	12.2
	Prior MI	11.2	11.0
	Prior ischemic stroke	10.6	10.3

For statin therapy to be favored, the RR of ICH would need to be less than or equal to 1.03 for primary prevention, 1.07 for secondary prevention after MI, and 1.06 for secondary prevention after ischemic stroke.

Other lipid lowering agents

- **Ezetimibe:** reduces LDL 15-20%. 20% RRR on MACE
- **Niacin:** reduces LDL by 12%/triglycerides 29%. 26% RRR in stroke
- **Icosapent ethyl:** 18% reduction in triglyceride. No evidence for benefit as monotherapy. Suggestion of perhaps excess bleeding and pleiotropic antiplatelet effect.
- **Fibrates:** No benefit as monotherapy. Pleiotropic antithrombotic therapies, including inhibition of tissue factor.

Canadian Stroke Best Practice Recommendations: Management of Spontaneous ICH

- There is no role for statin therapy in the secondary prevention of ICH. Statin therapy should not be initiated for secondary prevention of intracerebral hemorrhage [Evidence Level C].

- For intracerebral hemorrhage patients who have a clear concomitant indication for cholesterol lowering treatment, statin therapy should be individualized and should take into account the patient's overall thrombotic risk as well as the possibility of increased ICH risk with statin therapy.

Clinical Considerations

- An ongoing clinical trial (SATURN) addressing this question may potentially inform clinical decision-making for these patients. Until these results are available, decisions regarding statin therapy should be made based on risk/benefit ratio in consultation with an expert in cerebrovascular disease.

Statin treatment and accrual of covert cerebral ischaemia on neuroimaging: a systematic review and meta-analysis of randomized trials

A. H. Katsanos[a], V.-A. Lioutas[b], A. Charidimou[c], L. Catanese[a], K. K. H. Ng[a], K. Perera[a], D. de Sa Boasquevisque[a], G. Tsivgoulis[d,e], E. E. Smith[f], M. Sharma[a], M. H. Selim[b] and A. Shoamanesh[a]

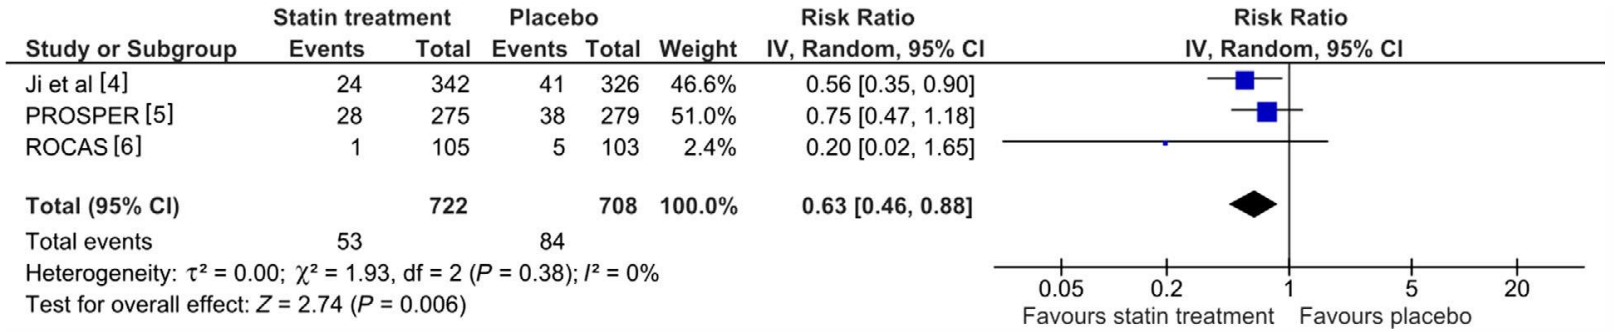

Figure 1 Risk of incident covert brain ischaemic infarcts in follow-up neuroimaging between individuals randomized to statin treatment or placebo. [Colour figure can be viewed at wileyonlinelibrary.com]

Conclusion

- Statins and lower cholesterol levels have been associated with greater risk of ICH – and likely play a causal role
  - Mendelian randomization and RCT meta-analyses
- The heterogeneity in the literature likely reflects heterogeneity in populations, study design, and residual confounding
- By targeting a lobar ICH population at high risk of recurrence, SATURN will likely be a landmark trial that answers the unresolved clinical question of statin continuation post ICH.
